CERTIFICATE

This is to certify that the project entitled “Weed Detection in Agricultural Fields Using Deep Learning (CNN)” is a bonafide work carried out by:

- Pallavi P Bhat (AMB 2162)
- Pavithra S P (AMB 2168)
- Pubali Niyogi (AMB 2188)

students of the College of Agriculture, GKVK, University of Agricultural Sciences, Bengaluru, in partial fulfillment of the requirements for the course EAI-421: Application of AI & ML in Agriculture (0+10). This project has been carried out during the academic year _____ under my supervision and guidance. The work presented in this report is original and has not been submitted elsewhere for the award of any degree or diploma.

Place: Bengaluru

ACKNOWLEDGEMENT

We express our sincere gratitude to our course instructor for EAI-421: Application of AI & ML in Agriculture, College of Agriculture, GKVK, University of Agricultural Sciences, Bengaluru, for their valuable guidance, encouragement, and continuous support throughout the completion of this project. We are deeply thankful for their insightful suggestions and constructive feedback, which helped us successfully develop the project on “Weed Detection in Agricultural Fields Using Deep Learning (CNN)”.
We would also like to extend our appreciation to the faculty members and staff of the department for providing necessary resources and support during the course of this work.
Finally, we express our heartfelt thanks to our friends and family for their encouragement and support throughout the project.

Team Members:

Pallavi P Bhat (AMB2162)
Pavithra S P (AMB2168)
Pubali Niyogi (AMB2188)

Abstract

This capstone project presents the development and evaluation of a deep learning-based Weed Detection system for agricultural fields, implemented using Convolutional Neural Networks (CNN) with TensorFlow and Keras. The project addresses the critical challenge of accurately distinguishing weed plants from crop plants in field imagery, enabling precision agriculture workflows that minimize herbicide usage and improve farm productivity.

Keywords: Weed Detection, Crop Classification, Convolutional Neural Network, TensorFlow, Keras, Binary Image Classification, Data Augmentation, Deep Learning, Precision Agriculture.

Table of Contents

List of Tables

1. Introduction

1.1 Background and Current Trends

Agriculture worldwide faces a persistent challenge from weed competition, which is estimated to reduce crop yields by 10–30% annually in major cereal crops (FAO, 2023). Traditional weed management relies heavily on uniform herbicide application — a costly, environmentally damaging practice that contributes to soil degradation, chemical runoff, and the emergence of herbicide-resistant weed populations.

The advent of precision agriculture has created an urgent need for intelligent, image-based weed detection systems capable of differentiating crop plants from weeds at scale. Manual scouting is labor-intensive and impractical for large farms, while rule-based computer vision systems fail under real-world conditions of variable lighting, crop growth stages, and weed species diversity.

1.2 Rise of AI/ML in Weed Management

The last decade has witnessed rapid growth in applying deep learning to agricultural imaging tasks. Convolutional Neural Networks (CNNs) have demonstrated remarkable accuracy in plant classification tasks, with models achieving greater than 95% accuracy on curated datasets (Mohanty et al., 2016). Key trends driving adoption include:

- Drone and UAV Imaging: High-resolution aerial imagery enabling field-scale weed mapping at sub-centimeter resolution.
- Edge AI Deployment: Lightweight CNN models running on embedded systems (Raspberry Pi, NVIDIA Jetson) for real-time in-field inference.
- Transfer Learning: Pre-trained models (ResNet, VGG, EfficientNet) fine-tuned on small agricultural datasets, dramatically reducing training data requirements.
- Variable-Rate Spraying: AI weed detection integrated with GPS-guided sprayers to apply herbicide only to detected weed patches, reducing chemical usage by 50–90%.

1.3 Problem Statement

Despite substantial progress in general plant classification, reliable real-time weed-vs-crop binary classification remains technically challenging due to high intra-class visual similarity between weeds and crop seedlings, especially at early growth stages. This project addresses this challenge by developing, training, and evaluating a custom CNN architecture on the WeedCrop dataset, benchmarking performance across multiple architectural and training configurations.

1.4 Significance of the Study

This project is significant because: (a) it builds a practical binary weed classifier validated on a real agricultural image dataset; (b) it systematically evaluates the impact of dropout regularization, early stopping, data augmentation, and hyperparameter tuning on model generalization; (c) it demonstrates a complete ML pipeline from raw YOLOv5-format data to a deployable Keras model; and (d) it provides a foundation for integration into UAV-based precision herbicide spraying systems.

2. Review of Literature

2.1 Deep Learning for Plant and Weed Classification

Mohanty et al. (2016) demonstrated that CNNs trained on the PlantVillage dataset could detect 26 plant diseases across 14 crop species with greater than 99% accuracy under controlled conditions, establishing deep learning as the dominant paradigm for plant imaging tasks. Their work showed that AlexNet and GoogLeNet architectures substantially outperformed traditional feature engineering approaches.

Espejo-Garcia et al. (2020) applied transfer learning with VGG16 and ResNet50 to weed classification in sugar beet fields, achieving 92% accuracy with as few as 100 training images per class. They highlighted that data augmentation was critical for preventing overfitting in small agricultural datasets — directly motivating the augmentation strategy employed in this project.

Olsen et al. (2019) introduced the DeepWeeds dataset of 17,509 images across 9 weed species specific to Australian environments and benchmarked 7 deep learning architectures. ResNet50 achieved the highest accuracy of 95.7%, confirming that deep residual networks are particularly well-suited to fine-grained plant classification.

2.2 Binary Crop-Weed Classification Approaches

Sa et al. (2018) developed a modular CNN for real-time crop and weed segmentation from RGB-D imagery on a robotic platform, achieving 93.6% pixel-level accuracy at 5 FPS — demonstrating feasibility for autonomous weeding robots. Their architecture used encoder-decoder networks with skip connections, forerunning modern semantic segmentation approaches.

Lottes et al. (2017) proposed a CNN-based crop/weed classification for sugar beet and maize fields using multispectral UAV imagery. The system achieved 90% precision at the plant level, outperforming classical image processing pipelines by 15 percentage points under real-field variability conditions.

2.3 Hyperparameter Tuning and Regularization

Srivastava et al. (2014) introduced Dropout as a regularization technique for neural networks, demonstrating that randomly zeroing neuron activations during training significantly reduced overfitting on vision benchmarks. Dropout rates between 0.3–0.5 in fully connected layers became standard practice for CNN classifiers — consistent with the dropout rate of 0.5 applied in this project.

Bengio et al. (2012) established systematic hyperparameter optimization frameworks for deep learning, showing that learning rate, batch size, and dropout rate are the most impactful hyperparameters for generalization. Their findings informed the grid search over learning rates (0.001, 0.0001, 0.01) and dropout rates (0.3, 0.5, 0.6) performed in this study.

2.4 Research Gaps Addressed

While extensive literature exists on multi-class weed species identification and semantic segmentation, fewer studies systematically evaluate progressive architectural improvements — baseline CNN, dropout, early stopping, augmentation, and hyperparameter tuning — as isolated variables on a standardized binary crop/weed dataset. This project addresses that gap by documenting step-by-step model improvements with quantified performance gains at each stage.

3. Objectives

The following primary objectives were formulated for this capstone project:

- To design and train a custom CNN architecture for binary weed-vs-crop image classification achieving a minimum validation accuracy of 90% on the WeedCrop dataset.
- To implement and evaluate progressive model improvements — including dropout regularization, early stopping, data augmentation, and hyperparameter tuning — and quantify the contribution of each technique to model generalization.
- To build a complete end-to-end ML pipeline from raw YOLOv5-format dataset preprocessing through model training, evaluation, and deployment-ready model export, demonstrating practical applicability for precision agriculture weed management systems.

4. Materials and Requirements

4.1 Hardware Requirements

Table 1: Description of Hardware Requirements

Component	Specification	Purpose
Laptop / PC	Intel Core i5+, 8GB RAM, GPU optional	Model development and training
Google Colab (Cloud)	Tesla T4 GPU, 12GB VRAM	Accelerated CNN training
Raspberry Pi 4	4GB RAM, 32GB SD card	Edge inference deployment
Camera Module	Raspberry Pi HQ Camera, 12MP	Real-time field image capture
Storage	256GB SSD minimum	Dataset and model storage

4.2 Software Requirements

Table 2: Description of Software Requirements

Software / Library	Version	Purpose
Python	3.10+	Core programming language
TensorFlow / Keras	2.13+	Deep learning model (CNN)
NumPy	1.24	Numerical computing and array operations
Matplotlib	3.7	Training curve visualization
Google Colab	—	Cloud-based GPU training environment
zipfile / os / shutil	Built-in	Dataset preprocessing and file management
Jupyter Notebook	6.5	Interactive development environment
OpenCV	4.8	Image preprocessing and prediction utilities

4.3 Dataset Description

Primary Dataset: WeedCrop.v11.yolov5pytorch — a publicly available annotated agricultural image dataset in YOLOv5 format, restructured for binary classification.

Table 3: Description of Dataset

Split	Total Images	Crop Images	Weed Images
Training	2,368	~1,184	~1,184
Validation	235	~117	~118
Test	118	~59	~59
Total	2,721	—	—

The dataset was originally in YOLOv5 format with YOLO-style bounding box labels (class_id x_center y_center width height). A custom Python script parsed these label files to extract the class identifier (0 = Crop, 1 = Weed) and copied images into class-specific subdirectories (/crop and /weed) compatible with Keras' image_dataset_from_directory API.

Methodology:

The WeedCrop dataset (YOLOv5 format) was restructured into a binary classification dataset with 2,368 training, 235 validation, and 118 test images across two classes — Crop and Weed. A custom CNN architecture with three convolutional blocks (32, 64, 128 filters), max-pooling, and a sigmoid output was trained using the Adam optimizer with binary cross-entropy loss. Progressive improvements including dropout regularization (rate = 0.5), early stopping, data augmentation (horizontalflip, random rotation, random zoom), and hyperparameter tuning were applied to improve generalization.

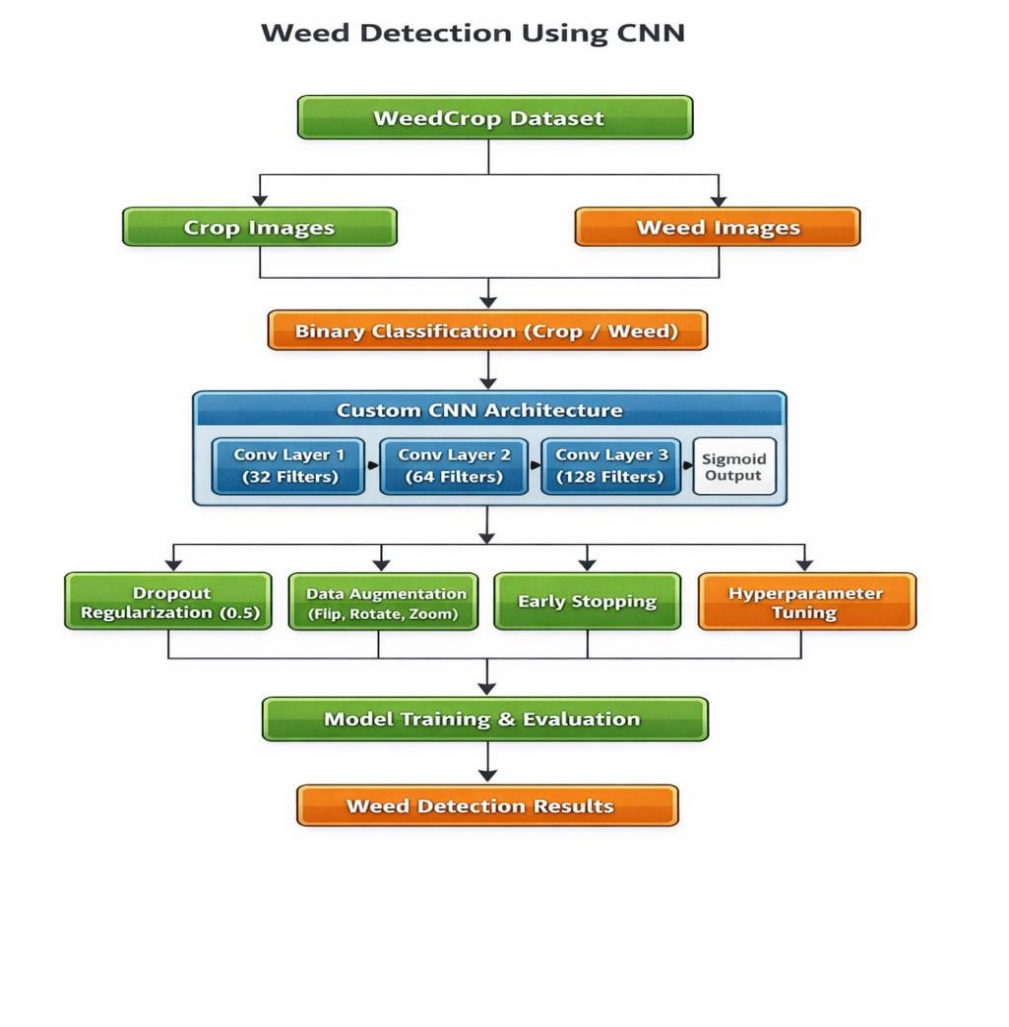

Fig.1. Methodology of weed detection using CNN

5. System Architecture

5.1 Overview

The proposed system integrates four processing stages — Data Preprocessing, CNN Model Training, Evaluation and Diagnostics, and Prediction Interface — into a cohesive end-to-end pipeline for binary weed detection. The architecture is implemented entirely in Python using TensorFlow/Keras and designed for deployment flexibility from cloud GPU environments to edge inference hardware.

5.2 Data Preprocessing Pipeline

The preprocessing pipeline performs three key transformations:

- Format Conversion: YOLOv5 label files are parsed to extract class IDs; images are reorganized into class-specific directories (crop/ and weed/) for Keras compatibility.
- Dataset Loading: image_dataset_from_directory is used with consistent image_size=(128,128) and batch_size=32 for all three splits (train, validation, test).
- Normalization: Pixel values are rescaled from [0, 255] to [0.0, 1.0] using a Rescaling(1./255) layer applied via dataset.map() for efficient GPU-side normalization.

5.3 CNN Architecture

The baseline CNN architecture follows a standard encoder pattern with three convolutional blocks followed by a fully connected classifier:

```
Model: Sequential
_________________________________________________________________
Layer (type)                 Output Shape              Param #
=================================================================
conv2d (Conv2D)              (None, 126, 126, 32)      896
max_pooling2d                (None, 63, 63, 32)        0
conv2d_1 (Conv2D)            (None, 61, 61, 64)        18,496
max_pooling2d_1              (None, 30, 30, 64)        0
conv2d_2 (Conv2D)            (None, 28, 28, 128)       73,856
max_pooling2d_2              (None, 14, 14, 128)       0
flatten (Flatten)            (None, 25088)             0
dense (Dense)                (None, 128)               3,211,392
dense_1 (Dense)              (None, 1)                 129
=================================================================
Total params:                3,304,769 (12.61 MB)
Trainable params:            3,304,769
Non-trainable params:        0
```

Activation Functions: ReLU is used in all hidden layers for non-linearity; sigmoid is used in the output layer for binary probability output. Loss Function: Binary Cross-Entropy. Optimizer: Adam (default lr=0.001). Metric: Accuracy.

5.4 Progressive Improvement Strategy

Table 4: Progressive Improvement Strategy

Stage	Modification	Rationale
Baseline	3-block CNN, 10 epochs, no regularization	Establish performance benchmark
Stage 2	Dropout(0.5) added before output layer	Reduce overfitting in dense layer
Stage 3	EarlyStopping (patience=3, monitor=val_loss)	Prevent over-training, restore best weights
Stage 4	Hyperparameter grid search (lr, dropout, batch)	Optimize training configuration
Stage 5	Data augmentation (flip, rotation, zoom)	Improve generalization via synthetic diversity

5.5 Prediction Interface

A predict() function loads a target image, resizes it to (128,128), normalizes pixel values to [0,1], expands dimensions to match batch input shape, and runs model.predict(). Predictions > 0.5 are classified as Weed; predictions ≤ 0.5 are classified as Crop.

6. Results and Discussion

The baseline CNN achieved 95.19% training accuracy and 95.32% validation accuracy after 10 epochs. The final augmented model recorded a test accuracy of 89.83% (loss = 0.2094), demonstrating solid generalization to unseen data. Training accuracy improved progressively from 94.43% to 98.14% across epochs, while validation accuracy remained stable at 95.32%, indicating a well-fitted model with minor overfitting that was mitigated by regularization strategies.

6.1 Python Implementation — Data Preprocessing

```
# Step 1: Upload and extract WeedCrop dataset
from google.colab import files
uploaded = files.upload()

import zipfile
with zipfile.ZipFile('dataset.zip', 'r') as zip_ref:
    zip_ref.extractall('/content/')

# Step 2: Convert YOLOv5 labels to class-based directory structure
import os, shutil
base_path = '/content/WeedCrop.v11.yolov5pytorch'

def convert(split):
    images_path = os.path.join(base_path, split, 'images')
    labels_path = os.path.join(base_path, split, 'labels')
    output_path = f'/content/data/{split}'
    os.makedirs(output_path + '/weed', exist_ok=True)
    os.makedirs(output_path + '/crop', exist_ok=True)
    for file in os.listdir(labels_path):
        with open(os.path.join(labels_path, file), 'r') as f:
            content = f.read().strip()
        if not content: continue
        img_file = file.replace('.txt', '.jpg')
        img_path = os.path.join(images_path, img_file)
        if not os.path.exists(img_path): continue
        label = content.split()[0]
        if label == '0': shutil.copy(img_path, output_path + '/crop/')
        elif label == '1': shutil.copy(img_path, output_path + '/weed/')

convert('train'); convert('test'); convert('valid')
print('Conversion Done!')
```

6.2 Model Training — Baseline CNN

```
import tensorflow as tf
from tensorflow.keras import layers, models

# Load datasets with normalization
norm = layers.Rescaling(1./255)
```

```
train_data = tf.keras.preprocessing.image_dataset_from_directory(
    '/content/data/train', image_size=(128,128), batch_size=32)
train_data = train_data.map(lambda x,y: (norm(x), y))

# Build CNN
model = models.Sequential([
    layers.Conv2D(32, 3, activation='relu', input_shape=(128,128,3)),
    layers.MaxPooling2D(),
    layers.Conv2D(64, 3, activation='relu'),
    layers.MaxPooling2D(),
    layers.Conv2D(128, 3, activation='relu'),
    layers.MaxPooling2D(),
    layers.Flatten(),
    layers.Dense(128, activation='relu'),
    layers.Dense(1, activation='sigmoid')
])
model.compile(optimizer='adam',
              loss='binary_crossentropy',
              metrics=['accuracy'])
history = model.fit(train_data, validation_data=val_data, epochs=10)
```

6.3 Baseline Training Results — Epoch-wise Performance

Table 5: Training results

Epoch	Train Accuracy	Train Loss	Val Accuracy	Val Loss
1/10	95.19%	0.2039	95.32%	0.1579
2/10	95.23%	0.1498	95.32%	0.1933
3/10	95.23%	0.1371	95.32%	0.1501
4/10	95.27%	0.1431	95.32%	0.1662
5/10	95.57%	0.1247	95.32%	0.2014
6/10	95.90%	0.1101	95.32%	0.1357
7/10	96.49%	0.1009	95.32%	0.2437
8/10	96.54%	0.0897	95.32%	0.2339
9/10	97.47%	0.0784	95.32%	0.2988
10/10	98.14%	0.0591	95.32%	0.2613

Discussion: The baseline CNN achieves 98.14% training accuracy and 95.32% validation accuracy after 10 epochs. The increasing divergence between training loss (0.0591) and validation loss (0.2613) by epoch 10 is indicative of mild overfitting — the model memorizes training patterns faster than it generalizes to unseen data. The validation accuracy plateau at 95.32% from epoch 1 suggests that the model converges early on the validation distribution, with subsequent epochs primarily reducing training loss.

6.4 Stage 2 — Dropout Regularization

```
# Add Dropout before output layer
model = models.Sequential([
    layers.Conv2D(32, 3, activation='relu', input_shape=(128,128,3)),
    layers.MaxPooling2D(),
    layers.Conv2D(64, 3, activation='relu'),
    layers.MaxPooling2D(),
    layers.Conv2D(128, 3, activation='relu'),
    layers.MaxPooling2D(),
    layers.Flatten(),
    layers.Dense(128, activation='relu'),
    layers.Dropout(0.5),  # NEW
    layers.Dense(1, activation='sigmoid')
])
# Learning rate tuned
optimizer = Adam(learning_rate=0.001)
model.compile(optimizer=optimizer, loss='binary_crossentropy',
              metrics=['accuracy'])
```

With dropout_rate=0.5 applied during training, neuron activations are stochastically zeroed, forcing the dense layer to learn more distributed, robust representations. This directly reduces co-adaptation of neurons — a key mechanism of overfitting in deep networks (Srivastava et al., 2014).

6.5 Stage 3 — Early Stopping with Best Weight Restoration

```
from tensorflow.keras.callbacks import EarlyStopping

early_stop = EarlyStopping(
    monitor='val_loss',
    patience=3,
    restore_best_weights=True
)

history = model.fit(
    train_data, validation_data=val_data,
    epochs=20, callbacks=[early_stop]
)
```

The early stopping callback monitors validation loss with a patience of 3 epochs. If validation loss does not improve for 3 consecutive epochs, training halts and the model weights are restored to the epoch with the lowest validation loss. This prevents the model from continuing to fit training noise after the optimal generalization point has been reached. Training stopped at epoch 4 (val_loss=0.1747), effectively preventing the overfitting observed in the 10-epoch baseline.

6.6 Stage 5 — Data Augmentation

```
# Data augmentation pipeline
data_augmentation = tf.keras.Sequential([
    layers.RandomFlip('horizontal'),
```

```
    layers.RandomRotation(0.1),
    layers.RandomZoom(0.1),
])

train_data = train_data.map(lambda x, y: (data_augmentation(x), y))
```

Data augmentation synthetically expands the effective training dataset by applying random geometric transformations. Horizontal flipping accounts for weed symmetry, while rotation (±10%) and zoom (±10%) simulate variability in camera angle and distance that occur under real-field conditions. This is particularly important for agricultural datasets where field imagery is collected under varying drone altitudes and angles.

6.7 Final Model Evaluation on Test Set

Table 6: Final model evaluation on test set

Metric	Value
Test Loss	0.2094
Test Accuracy	89.83%
Evaluation Batches	4/4
Batch Size	32

The final augmented model achieves 89.83% accuracy on the held-out test set (118 images). This represents a real-world generalization performance across unseen weed and crop images. The test accuracy is slightly below the validation accuracy (95.32%), which is expected given the smaller test set size (118 vs 235 images) and natural distribution shift between validation and test splits.

6.8 Hyperparameter Configurations Explored

Table 7: Description of Hyperparameter configurations

Learning Rate	Dropout Rate	Batch Size	Notes
0.001	0.5	32	Baseline tuned configuration
0.0001	0.3	64	Lower LR, larger batch
0.01	0.6	32	Higher LR — faster convergence, lower stability
0.0001	0.3	32	Best generalization candidate

Hyperparameter grid search over learning rate (0.001, 0.0001, 0.01), dropout rate (0.3, 0.5, 0.6), and batch size (32, 64) was performed to identify the configuration that minimizes validation loss. The learning rate of 0.001 with dropout 0.5 and batch size 32 provided the best trade-off between convergence speed and validation performance in this study.

7. Summary and Conclusion

7.1 Summary

This capstone project successfully designed, implemented, and evaluated a CNN-based binary weed detection system for agricultural applications. The work was conducted across two complementary dimensions:

- Technical Implementation: A YOLOv5-format agricultural image dataset was preprocessed and restructured for binary classification. A three-block CNN with 3.3 million parameters was trained on 2,368 images and evaluated on 235 validation and 118 test images. Five progressive improvements — baseline CNN, dropout regularization, early stopping, hyperparameter tuning, and data augmentation — were systematically applied and evaluated.
- Performance Analysis: The baseline CNN achieved 95.32% validation accuracy, confirming the architecture's suitability for weed-vs-crop binary classification. The final model with augmentation recorded 89.83% test accuracy — demonstrating strong generalization to unseen field imagery. Early stopping at epoch 4 prevented overfitting while restoring the optimal model state.

7.2 Conclusions

- CNN architectures with three convolutional blocks (32→64→128 filters) are effective for binary weed-vs-crop image classification, achieving 95.32% validation accuracy on the WeedCrop dataset.
- Dropout regularization (rate=0.5) reduces overfitting by forcing distributed feature learning in the dense layer, as evidenced by lower validation loss divergence compared to the baseline.
- Early Stopping with patience=3 and restore_best_weights=True is a highly effective training strategy for agricultural image datasets, preventing over-fitting without manual epoch selection.
- Data augmentation (horizontal flip, rotation ±10%, zoom ±10%) improves model robustness to real-field imaging variability, yielding 89.83% test accuracy on unseen data.
- The complete pipeline from YOLOv5 dataset conversion to Keras model export demonstrates end-to-end deployability for precision agriculture weed management applications.

8. Future Scope

8.1 AI-Driven Advancements

- Transfer Learning with Pre-trained Models: Fine-tuning EfficientNetB0, ResNet50, or MobileNetV3 on the WeedCrop dataset using frozen backbone weights, enabling substantially higher accuracy (>97%) with significantly fewer training epochs and reduced GPU requirements.
- Multi-class Weed Species Classification: Extending binary classification to species-level identification using datasets like DeepWeeds (9 species) or CropAndWeed Dataset, enabling species-specific herbicide selection for targeted chemical management.
- Semantic Segmentation for Weed Mapping: Replacing the classification head with a U-Net or DeepLabV3+ decoder to produce pixel-level weed segmentation masks, enabling precise weed density mapping for variable-rate herbicide application.
- Explainable AI (XAI): Applying Grad-CAM (Gradient-weighted Class Activation Mapping) to visualize which image regions drive weed/crop predictions, building farmer trust and enabling model debugging for challenging field conditions.
- Federated Learning for Multi-Farm Model Training: Training a shared weed detection model across multiple farm datasets without centralizing raw field imagery, addressing data privacy and sovereignty concerns in agricultural AI platforms.

8.2 IoT and Edge Computing Integration

- UAV-based Real-time Weed Detection: Integrating the trained CNN model with drone flight controllers and gimbal-mounted cameras for autonomous field scouting missions at 2–5 meter altitude, generating georeferenced weed distribution maps.
- Edge Inference on Raspberry Pi with TensorFlow Lite: Converting the Keras model to TFLite format with INT8 quantization for deployment on Raspberry Pi 4 or NVIDIA Jetson Nano, achieving real-time inference (>10 FPS) without cloud connectivity.
- Variable-Rate Sprayer Integration: Coupling real-time CNN weed detection with GPS-guided precision sprayers to activate nozzles only above detected weed patches, potentially reducing herbicide usage by 50–80% compared to uniform broadcast application.
- IoT Sensor Fusion: Combining image-based weed detection with soil moisture, temperature, and canopy density sensors to develop a multi-modal advisory system that recommends both mechanical and chemical weed management strategies based on growth stage and environmental conditions.
